

Unusual external service or program

When you are installing an application for Android. It has to be approved by Google Application Store.

In case, application is approved, then it is ready to start being commercialized.

Application's features could be caught by other programs, which are running in other devices.

These application's features use Wi-Fi, NFC or other services from user smart device.

These mentioned external programs could try to manipulate and do what want them to do.

That could be a vulnerability.

Solution could be writing a light program in any language, like for example: C++, Java, so on.

This program should review, if features that application is using, it is been using by the application recently installed by user.

This mentioned program (coded in C++/Java) should keep searching, whether any external service or program, it is trying to catch the same features,

and consequently aborting the running of these external services or programs.
